## ABSTRACT

The CeO<sub>2</sub> NPs were derived from *Azadirachta indica* (A.indica) leaf extracts. The X-ray diffraction studies confirmed that synthesized CeO<sub>2</sub> NPs were exhibited the cubic structure. In XPS spectra, the oxidation states of each element were identified for CeO<sub>2</sub> NPs. The Raman active mode was observed at 461cm<sup>-1</sup>, and this was due to the symmetrical stretching mode of the Ce-8O for CeO<sub>2</sub> NPs. From FESEM and TEM images, the CeO<sub>2</sub> NPs were exhibited a spherical structure. From the EDAX spectra, the elemental compositions were identified. The optical studies were carried out using UV-Vis and Photoluminescence spectra for CeO<sub>2</sub> NPs, respectively.

**Keywords:** Photosynthesis; CeO<sub>2</sub>; Nanoparticles; Optical studies.

## 1. INTRODUCTION

The CeO<sub>2</sub> nanoparticles could be a technologically potent material with remarkable properties utilized in a variety of applications in Environmental science. The CeO<sub>2</sub> nanoparticles have been used as three-way catalysts (TWC) for exhaust gas treatment from automobiles, oxygen ion conductors in solid oxide fuel cells, polishing agents for the chemical, mechanical planarization (CMP) process, gate oxides in metal oxide semiconductor devices, and ultraviolet (UV) blocking materials in UV shielding, respectively (Zhang *et al.* 2003; Si *et al.* 2005; Yu *et al.* 2005; Wang *et al.* 2003; Miki *et al.* 1990; Tsunekawa *et al.* 2000).

The synthesized CeO<sub>2</sub> NPs were prepared by physical and chemical methods such as hydrothermal, flame spray pyrolysis, sonochemical, microwave, sol-gel, and co-precipitation (Zhang *et al.* 2003; Hu *et al.* 2007; Wang *et al.* 2002; Liao *et al.* 2001; Czerwinski *et al.* 1997; Yao and Xie, 2007). However, most of the techniques are difficult, time-intensive, high priced, and unsafe. Green chemistry approaches the event in photosynthesis of metal and metal oxide NPs. This method offers several benefits like cost-effectiveness, large-scale industrial production, and pharmaceutical applications.

In the present investigation, CeO<sub>2</sub> NPs are prepared through the *Azadirachta indica* leaf extract. The

synthesized nanoparticles are characterization work done by the structural, morphological, and optical CeO<sub>2</sub> NPs.

### 1.1 Material and Methods

#### 1.1.1 Green synthesis CeO<sub>2</sub> NPs

The 10 g of finely divided leaves of *Azadirachta indica* was added to 100 mL of double distilled water and boiled at 50-60°C for 10 min. The solution was filtered through Whatmann No. 1 filter paper, and the clear filtrate was collected and which were carried for further usage. Thereafter, add a certain quantity of 0.1M solution of cerium nitrate to 100 mL of *A. indica* leaf extract with constant stirring at 80 °C for 6h. The Initially brown precipitate was formed, and then it becomes a yellowish-brown in color on continuous stirring. Finally, the precipitate was dried at 120 °C. The precipitate was annealed at 400 °C for 5h to get spherical NPs.

#### 1.1.2 Characterization techniques

The CeO<sub>2</sub> NPs were characterized by an X-ray diffractometer (model: X'PERT PRO PANalytical). The diffraction patterns were recorded in the range of 20°-80° for the CeO<sub>2</sub> NPs samples, where the monochromatic wavelength of 1.54 Å was used. The XPS measurements were performed with an XPS instrument (Carl Zeiss) equipment. The spectra were at a pressure using an ultra-

high vacuum with Al K $\alpha$  excitation at 250 W. The samples were analyzed by Field Emission Scanning Electron Microscopy (Carl Zeiss Ultra 55 FESEM) with EDAX (model: Inca). TEM analyses were carried out by the instrument Philips CM 200 model operated at an accelerating voltage of 20-200kv Resolution: 2.4 Å. The FT-IR spectra were recorded in the range of 400-4000 cm<sup>-1</sup> by using a Perkin-Elmer spectrometer. The absorption spectra of CeO<sub>2</sub>NPs were studied in the range between 200 and 800nm by Lambda 35 spectrometers. Photoluminescence spectra were measured using the Cary Eclipse spectrometer.

## 2. RESULTS & DISCUSSIONS

### 2.1 Structural Analysis

The X-ray diffraction patterns of CeO<sub>2</sub> NPs derived from *A. indica* leaf extract are shown in Fig. 1. The standard diffraction peaks show the face-center cubic phase of CeO<sub>2</sub> NPs (JCPDS data Cardno: 34-0394). The lattice constant 'a' values are 5.4108 Å for CeO<sub>2</sub> NPs. The average crystallite sizes are found to be 9.2 nm. The XPS of CeO<sub>2</sub> NPs derived from *A. Indica* leaf extract is shown in Fig. 2. The XPS provides information on the oxidation state of each element in the sample as well as the composition of the surface functionalization of the CeO<sub>2</sub>NPs. The XPS results show that the indexed peaks correspond to the C (1s), O (1s), and Ce (3d) for the CeO<sub>2</sub> NPs. The C (1s) signals are most likely due to trace amounts of plant or simply due to the absorption of organic contaminants. The Raman spectra of CeO<sub>2</sub> NPs derived from *A. Indica* leaf extract are shown in Fig. 3. From the Raman spectra, the sharp Raman active mode is observed at 461cm<sup>-1</sup>. This is due to the symmetrical stretching mode of the Ce-8O for CeO<sub>2</sub> NPs. However, this peak is very sensitive to any disorder in the oxygen sub-lattice results, changing in physical and chemical properties (Arumugam *et al.*; 2015).

### 2.2 Morphological and Elemental Analysis

The surface morphology and elemental composition of CeO<sub>2</sub> NPs derived from *A. Indica* leaf extract are shown in Fig. 4(a-b). The FESEM and TEM image clearly shows the average sizes of the NPs are in 5-6 nm range. The CeO<sub>2</sub> NPs exhibit a spherical structure. From the EDAX spectra (see fig. 4c) CeO<sub>2</sub> NPs, the atomic percentage of Ce, C, and O were found to be 64.03 %, 20.15%, and 15.82%, respectively.

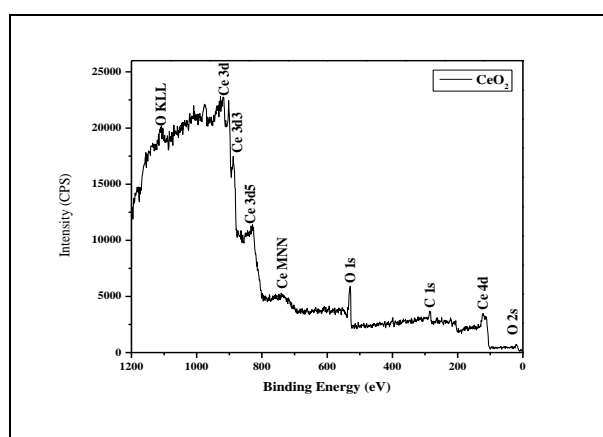

Fig. 2: XPS spectra of CeO<sub>2</sub> NPs.

Fig. 3: FT-Raman spectra of CeO<sub>2</sub> NPs.

Fig. 4: (a-c) Morphology images of (a) FESEM, (b) TEM and (c) EDAX spectra of CeO<sub>2</sub> NPs.

### 2.3 Optical Studies

The UV-VIS spectra of CeO<sub>2</sub> NPs derived from *A. indica* leaf extract are shown in Fig. 5. *A. indica* leaf extract consists of phytoconstituents acting as a capping and reducing agent. So, it has reduced to form the CeO<sub>2</sub> NPs. The absorption edge is observed at 314 nm for CeO<sub>2</sub> sample. This can be attributed to the photoexcitation of electrons from the valence band to the conduction band.

Fig. 5: UV-Vis absorption spectra of CeO<sub>2</sub> NPs.

The photoluminescence spectra of the CeO<sub>2</sub> NPs derived from *A. indica* leaf extract were recorded with the exciting wavelength of 325 nm. The emission spectra of CeO<sub>2</sub> NPs are obtained with eight peaks at 360 nm, 375 nm, 391 nm, 411 nm, 442 nm, 452 nm, 491 nm, and 519 nm, which are shown in (Fig. 6). The spectra comprise of the three near band edge emission (360 nm, 375 nm, and 391 nm), violet emission (411 nm), two blue emissions (442 nm and 452 nm), blue-green emission (491 nm), and green emission (512 nm) for CeO<sub>2</sub> NPs respectively.

The NBE emission 360 nm, 375 nm, and 391 nm are attributed to a band-to-band recombination process, which possibly involving localized or free exciton (Wang *et al.* 2011). These emission peaks

between 400 and 500 nm form a broad emission band. The violet emission band 411 nm is originated from the defect state existing extensively between the Ce 4f band and O 2p band (Morshed *et al.* 1997 and Lu *et al.* 2010). The blue emission bands (442 nm and 452 nm) can be attributed to the excitonic recombination of CeO<sub>2</sub> NPs (Huang *et al.* 2011 and Kim. 2001) and can be partly certified by comparing the relationship of peak intensity and bandgap. They are due to the 5d-4f transitions of Ce<sup>3+</sup> between the <sup>2</sup>D (5d<sup>1</sup>) ground state and the <sup>2</sup>F<sub>5/2</sub> (4f<sup>1</sup>) state. The blue-green emission bands (491 nm) are attributed to the transitions from different defect levels of the O 2p band. The green emission bands (512 nm) may be due to the low density of oxygen vacancies during the preparation of the CeO<sub>2</sub> NPs.

Fig. 6: Photoluminescence spectra of CeO<sub>2</sub> NPs.

### 3. CONCLUSION

The CeO<sub>2</sub> NPs were synthesized by the green method derived from *A. Indica* leaf extract. X-ray diffraction study confirmed that the prepared particles were of the cubic fluorite structure of CeO<sub>2</sub> NPs. The XPS studies showed that from the indexed peaks corresponding to Ce (3d), C (1s), and O (1s), the

respective binding energies of the elements were estimated. From the FT-Raman spectra, the sharp Raman active mode was observed at  $461\text{cm}^{-1}$ , and this was due to the symmetrical stretching mode of the Ce-8O for CeO<sub>2</sub> NPs. From the TEM and FESEM images, the morphology of CeO<sub>2</sub> nanoparticles exhibits a spherical structure. The elemental compositions identify by EDAX spectra. In UV-Vis absorption spectra, the peak edge was observed at 314 nm for CeO<sub>2</sub> NPs. From the PL spectra, the low intense band edge emission peaks were obtained due to the energy released by the electrons coming down from Ce 4f level to O 2p level.
